Colimits of effect algebras via a reflection

TACL 2019 1 / 34

An *effect algebra* is a partial algebra (E; +, 0, 1) satisfying the following conditions.

- (E1) If a + b is defined, then b + a is defined and a + b = b + a.
- (E2) If a + b and (a + b) + c are defined, then b + c and a + (b + c) are defined and (a + b) + c = a + (b + c).
- (E3) For every $a \in E$ there is a unique $a^{\perp} \in E$ such that $a + a^{\perp} = 1$. (E4) If a + 1 exists, then a = 0

Let E be an effect algebra.

- Cancellativity: $a + b = a + c \Rightarrow b = c$.
- Partial difference: If a + b = c then we write a = c b. The operation is well defined and $a^{\perp} = 1 a$.
- *Poset:* Write $b \le c$ iff $\exists a : a + b = c$; (E, \le) is then a bounded poset.

The class of effect algebras includes

- orthomodular lattices
- MV-algebras
- Boolean algebras.

Definition

Let A be an effect algebra, let $\sim \subseteq A \times A$ be a relation such that the following conditions are satisfied.

- $\circ \sim$ is an equivalence.
- If $x_1 \sim x_2$ and $y_1 \sim y_2$ and $x_1 + y_1$ exists and $y_1 + y_2$ exists, then $x_1 + y_1 \sim x_2 + y_2$.
- If $x_1 \sim x_2$, then $x_1^{\perp} \sim x_2^{\perp}$.

Then we say that \sim is *a congruence* on *A*.

Definition

Let E, F be effect algebras, let $f : A \rightarrow B$. We say that f is a morphism of effect algebras iff

- f(1) = 1 and
- for all $x, y \in A$ such that x + y exists in A, f(x) + f(y) exists in Band f(x + y) = f(x) + f(y)

Whenever $f : A \to B$ is a morphism of effect algebras, its kernel $\Theta_f \subseteq A \times A$, given by

$$x\Theta_f y \Longleftrightarrow f(x) = f(y)$$

is a congruence.

In non-partial algebras:

- there is a quotient algebra A/Θ
- and a mapping

 $x\mapsto [x]_\Theta$

that takes every element to its equivalence class.

- For effect algebras, the quotient A/Θ might be non-associative.
- The problem is *existence* of sums, not their value.

• We may try to come up with sufficient conditions on Θ under which A/Θ is an effect algebra.

- We may try to come up with sufficient conditions on Θ under which A/Θ is an effect algebra.
- The general idea is to enforce the existence of sums by adding some conditions to the definition of the congruence.

- We may try to come up with sufficient conditions on Θ under which A/Θ is an effect algebra.
- The general idea is to enforce the existence of sums by adding some conditions to the definition of the congruence.
- Examples
 - Strong: if $x_1 \Theta x_2$ and $x_1 + y$ exists, then $x_2 + y$ exists.

- We may try to come up with sufficient conditions on Θ under which A/Θ is an effect algebra.
- The general idea is to enforce the existence of sums by adding some conditions to the definition of the congruence.
- Examples
 - Strong: if $x_1 \Theta x_2$ and $x_1 + y$ exists, then $x_2 + y$ exists.
 - Weaker: if $x_1 \Theta x_2$ and $x_1 + y_1$ exists, then there is $y_2 \Theta y_1$ such that $x_2 \Theta y_2$ exists.

- We may try to come up with sufficient conditions on Θ under which A/Θ is an effect algebra.
- The general idea is to enforce the existence of sums by adding some conditions to the definition of the congruence.
- Examples
 - Strong: if $x_1 \Theta x_2$ and $x_1 + y$ exists, then $x_2 + y$ exists.
 - Weaker: if $x_1 \Theta x_2$ and $x_1 + y_1$ exists, then there is $y_2 \Theta y_1$ such that $x_2 \Theta y_2$ exists.
 - Ideals: we might consider only quotients by ideals.

- We may try to come up with sufficient conditions on Θ under which A/Θ is an effect algebra.
- The general idea is to enforce the existence of sums by adding some conditions to the definition of the congruence.
- Examples
 - Strong: if $x_1 \Theta x_2$ and $x_1 + y$ exists, then $x_2 + y$ exists.
 - Weaker: if $x_1 \Theta x_2$ and $x_1 + y_1$ exists, then there is $y_2 \Theta y_1$ such that $x_2 \Theta y_2$ exists.
 - Ideals: we might consider only quotients by ideals.
- This area was explored around the year 2000 by Gudder, Chevalier, Pulmannová, GJ in several papers.

Congruences, from a categorical viewpoint

• A congruence on an algebra A can be characterized as a *subalgebra of* $A \times A$ that (as a relation) is an equivalence:

$$\Theta \longrightarrow A \times A$$

Congruences, from a categorical viewpoint

• A congruence on an algebra A can be characterized as a *subalgebra of* $A \times A$ that (as a relation) is an equivalence:

$$\Theta \longrightarrow A \times A$$

• Composing this embedding with two projections $A \times A \rightarrow A$

$$\Theta \longrightarrow A \times A \Longrightarrow A$$

Congruences, from a categorical viewpoint

• A congruence on an algebra A can be characterized as a *subalgebra of* $A \times A$ that (as a relation) is an equivalence:

$$\Theta \longrightarrow A \times A$$

• Composing this embedding with two projections $A \times A \rightarrow A$

$$\exists \hookrightarrow A \times A \Longrightarrow A$$

• gives us, in a canonical way, two mappings

$$\Theta \xrightarrow[p_2]{p_1} A$$

If we compose p_1, p_2 with the quotient map $q(x) = [x]_{\Theta}$

$$\Theta \xrightarrow[p_2]{p_1} A \xrightarrow{q} A / \Theta$$

we obtain an equality

$$q \circ p_1 = q \circ p_2$$

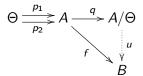

Moreover, q is the "best" mapping with respect to the equality $q \circ p_1 = q \circ p_2$, meaning

TACL 2019 13 / 34

Moreover, q is the "best" mapping with respect to the equality $q \circ p_1 = q \circ p_2$, meaning

• whenever
$$f \circ p_1 = f \circ p_2$$
,

• there is a unique arrow u making the diagram

commute.

That means, $q: A \rightarrow A/\Theta$ is a coequalizer of the pair

$$\Theta \xrightarrow{p_1}_{p_2} A$$

Problem

Does the category of effect algebras have coequalizers?

That means, $q: A \rightarrow A/\Theta$ is a coequalizer of the pair

$$\Theta \xrightarrow{p_1}_{p_2} A$$

Problem

Does the category of effect algebras have coequalizers?

Or, more generally:

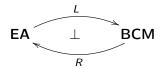

Problem

Does the category of effect algebras have all (small) colimits?

• Yes [Jacobs and Mandemaker 2012].

æ

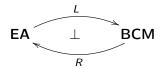

- Yes [Jacobs and Mandemaker 2012].
- There is a coreflection

between effect algebras EA and barred commutative monoids BCM.

• BCM is a quasivariety, so it has all coequalizers.

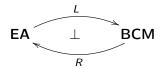

- Yes [Jacobs and Mandemaker 2012].
- There is a coreflection

between effect algebras EA and barred commutative monoids BCM.

- BCM is a quasivariety, so it has all coequalizers.
- So EA has all coequalizers, for general reasons.

- Yes [Jacobs and Mandemaker 2012].
- There is a coreflection

between effect algebras EA and barred commutative monoids BCM.

- BCM is a quasivariety, so it has all coequalizers.
- So EA has all coequalizers, for general reasons.
- EA has all coproducts (easy).

Moreover, Jacobs and Mandemaker have constructed an example of a non-surjective coequalizer

$$B \xrightarrow{g_1} A \xrightarrow{q} Q$$

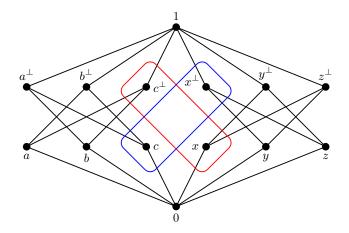

Moreover, Jacobs and Mandemaker have constructed an example of a non-surjective coequalizer

$$B \xrightarrow[g_2]{g_1} A \xrightarrow{q} Q$$

and one can easily adapt their example to show that there are "non-surjective" quotient maps:

$$\Theta \xrightarrow[\rho_2]{p_1} A \xrightarrow{q} A/\Theta$$

A congruence

The quotient is isomorphic to the Boolean algebra 2^4 .

• A finite multiset over a set X is a mapping

$$\mathbf{t}\colon X\to\mathbb{N}$$

with finite support.

- The set of all finite multisets over a set X is denoted by M(X).
- (M(X), +, 0) is a monoid (free commutative monoid generated by X).
- M(X) is partially ordered (pointwise).

A finite multiset system \mathcal{X} is a pair $(V(\mathcal{X}), T(\mathcal{X}))$, where $V(\mathcal{X})$ is a set called *the set of points of* \mathcal{X} and $T(\mathcal{X})$ is a set of finite multisets over $V(\mathcal{X})$, called *tests of* \mathcal{X} .

A morphism of finite multisets systems $f: \mathcal{X} \to \mathcal{Y}$ is a mapping $f: V(\mathcal{X}) \to V(\mathcal{Y})$ such that the *pushforward of a test* $t \in T(\mathcal{X})$ is a test of \mathcal{Y} :

$$f_*(t)(y) = \sum_{x \in f^{-1}(y)} t(x),$$

Theorem

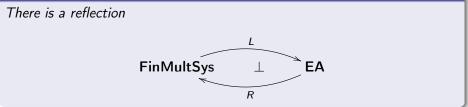

The category of finite multiset systems is complete and cocomplete.

Theorem

The category of finite multiset systems is complete and cocomplete.

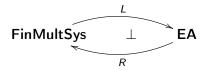

Importantly, the limits and colimits are *easy to compute*: there is an obviously defined functor **FinMultSys** \rightarrow **Set** that *creates all limits and colimits*.

Theorem

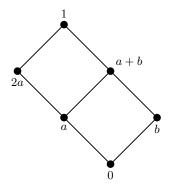

TACL 2019 24 / 34

- A 🖓

If A is an effect algebra, then R(A) is the set of all *decompositions of unit* (called the *tests of A*).

Example

0	а	b	2 <i>a</i>	a + b	1
0	2	1	0	0	0
0	0	1	1	0	0
5	1	0	0	1	0
3	0	0	0	0	1

3

- Let \mathcal{X} be a finite multiset system.
- An event of \mathcal{X} is a $V(\mathcal{X})$ -based multiset

 $a\colon V(\mathcal{X}) \to \mathbb{N}$

such that there is a test $t \in T(\mathcal{X})$ such that $a \leq t$.

- Let \mathcal{X} be a finite multiset system.
- An event of \mathcal{X} is a $V(\mathcal{X})$ -based multiset

 $a\colon V(\mathcal{X}) \to \mathbb{N}$

such that there is a test $t \in T(\mathcal{X})$ such that $a \leq t$.

• The set of all events is denoted by $E(\mathcal{X})$.

- Let \mathcal{X} be a finite multiset system.
- An event of \mathcal{X} is a $V(\mathcal{X})$ -based multiset

 $a\colon V(\mathcal{X}) \to \mathbb{N}$

such that there is a test $t \in T(\mathcal{X})$ such that $a \leq t$.

- The set of all events is denoted by $E(\mathcal{X})$.
- Two events $a, b \in E(\mathcal{X})$ are complements of each other if

$$a+b\in T(\mathcal{X})$$

- Let \mathcal{X} be a finite multiset system.
- An event of \mathcal{X} is a $V(\mathcal{X})$ -based multiset

a: $V(\mathcal{X}) \to \mathbb{N}$

such that there is a test $t \in T(\mathcal{X})$ such that $a \leq t$.

- The set of all events is denoted by $E(\mathcal{X})$.
- Two events $a, b \in E(\mathcal{X})$ are complements of each other if

$$a+b\in T(\mathcal{X})$$

• Two events a, a' are *perspective* (in symbols $a \sim a'$) if the share a common complement:

$$a+b\in T(\mathcal{X})$$
 $b+a'\in T(\mathcal{X})$

Definition

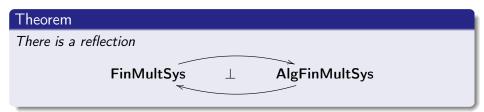

A finite multiset system is \mathcal{X} algebraic if

 $\bullet\,$ The set of tests of ${\mathcal X}$ is order-convex, that means

 $t_1, t_2 \in T(\mathcal{X}) \text{ and } t_1 \leq s \leq t_2 \implies s \in T(\mathcal{X}).$

• If $a \sim a'$ and a is a complement of c, then a' is a complement of c. In other words,

$$\left. \begin{array}{l} a'+b \in T(\mathcal{X}) \\ b+a \in T(\mathcal{X}) \\ a+c \in T(\mathcal{X}) \end{array} \right\} \implies a'+c \in T(\mathcal{X})$$

Colimits of effect algebras via a reflection

TACL 2019 29 / 34

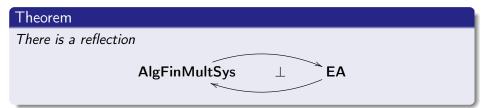

э

For every effect algebra A, the finite multiset system consisting of all decompositions of unit of A is algebraic.

- Let \mathcal{X} be an algebraic multiset system.
- The relation of perspectivity \sim on the set of all events $E(\mathcal{X})$ is an equivalence relation.
- Perspectivity behaves well with respect to sums of events:

$$a_1 \sim a_2$$
 and $b_1 \sim b_2 \implies a_1 + b_1 \sim a_2 + b_2$

• $E(\mathcal{X})/\sim$ forms an effect algebra.

TACL 2019 32 / 34

If time permits, we can compute a colimit $\mathcal{P}(\mathbb{Z})/\mathbb{Z}.$

Thank you for your attention.
